

Paragon and Horizon Stress Testing Session for Remote Hosted /Network Latency Validation

The Challenge

- To **provide a mechanism or software tool to provide Stress/Load/Latency testing.** McKesson also didn't have any software or recommendations on how to approach and determine if there was any type of application latency when a number of users were on the system.
- Since CMHS is the first Paragon/Horizon remote hosted site CMHS had **concerns regarding the potential application latency that might be experienced with a large number of users on the system.**

The Solution

- Conducted a **Stress Testing User Session with both CMHS and McKesson monitoring both their remote hosting connections and their system network connections with approximately 170 users validating both applications and reports.**

The Results

- With 170 users testing the system approximately 2% of the total system resource availability was used. System usage snapshots were taken during the one hour session to detect any latency.
